(54) **A method of reading out signals for a solid-state imaging device.**

(57) A method of reading out signals for a solid-state imaging device is disclosed. In this method, the timing of a final gate transfer clock signal ϕ_{H1}' and the timing of a reset pulse signal ϕ_R are both synchronized with two cycles of a horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , to combine signal charges from two horizontally adjacent pixel pairs. Accordingly, the sensitivity under a low light intensity can be enhanced in a simple and inexpensive way without modifying the structure of the solid-state imaging device or adding an external device.

Fig. 2

EP 0 498 662 A2

BACKGROUND OF THE INVENTION

1. Field of the Invention:

The present invention relates to a method of reading out signals for a solid-state imaging device used in a video camera, image pick-up device, or the like.

2. Description of the Prior Art

Nowadays, two-dimensional solid-state imaging devices using charge transfer means are widely used in broadcast and home video cameras and the like. To produce images using such two-dimensional solid-state imaging devices and conforming to the scanning system of television, 2:1 interlaced scanning must be performed in the two-dimensional imaging devices to conform to the 2:1 interlaced scanning system of television in which two fields are traced during each frame period. The following describes a method of reading out signals for a solid-state imaging device in which 2:1 interlacing in such a two-dimensional solid-state imaging device is achieved by a field-integration method.

Figure 6 shows a schematic diagram of an inter-line transfer charge-coupled (CCD) area/image sensor as an example of a two-dimensional solid-state imaging device in which 2:1 interlacing is achieved by a field-integration method. In the area/image sensor shown, a plurality of photoelectric converters 1, 1, ... each comprising a photodiode, an MOS transistor, etc. are arranged in a lattice-like array (i.e., an array of rows and columns) corresponding to the pixels of the television display system. When a gate pulse is applied to a transfer gate 2 during the vertical blanking period, charges generated by the photoelectric converters 1, 1, ... in proportion to the light intensity are simultaneously transferred into corresponding storage sites 3a, 3a, ... in vertical transfer sections 3 consisting of CCDs arranged in the vertical direction alternately with the vertical arrays of photoelectric converters 1, 1, After that, photoelectric conversion is performed once again by the photoelectric converters 1, 1, ..., so that the next set of signal charges proportional to the light intensity are accumulated.

During each horizontal blanking period, the signal charges transferred from the photoelectric converters 1, 1, ... to the corresponding storage sites 3a, 3a, ... in the vertical transfer sections 3 are transferred line by line, as shown by arrow (A), into corresponding storage sites (not shown) in a horizontal transfer section 4 consisting of a CCD array. The signal charges for one scanning line that have been transferred into the horizontal transfer section 4 are then clocked horizontally, as shown by arrow (B), toward the final stage transfer gate 6 by the clock timing shown in Figure 8. The signal charges for one field are thus output line by line from the final stage transfer gate 6 to a charge

detector 5, and the signal sensed by the charge detector 5 is amplified by an amplifier 7 to form a standard video signal.

Figure 7 is a cross sectional view of the horizontal transfer section 4, transfer gate 6, and charge detector 5 of Figure 6, with applied potentials indicated.

The above-mentioned field-integration method achieves 2:1 interlacing by reading out signals in the following manner. In the field-integration method, all the signal charges generated by the photoelectric converters (hereinafter referred to as pixels) to produce one frame are read out during one field period. To achieve this, signal charges from two vertically adjacent pixels 1a and 1b shown in Figure 6 (hereinafter simply referred to as "pixel pair") are combined and simultaneously read out into one storage site 3a in the adjacent vertical transfer section 3. For example, for an odd-numbered field, signal charges from a pixel 1a₁ and a pixel 1b₁ are combined and simultaneously transferred into one storage site 3a₁ in the adjacent vertical transfer section 3 (as shown by solid arrows in Figure 6); on the other hand, for an even-numbered field, signal charges from a pixel pair offset by one pixel in the vertical direction, i.e. the pixel 1b₁ and a pixel 1a₂, are combined and simultaneously transferred into the storage site 3a₁ (as shown by dotted arrows in Figure 6). As a result, as shown in Figure 9, apparent space sampling points for an odd-numbered field are each taken at the middle point (indicated by a circle numbered "1") between two vertically adjacent pixels 1a and 1b constituting each pixel pair in areas 31 defined by thin solid lines, while apparent space sampling points for an even-numbered field are each taken at the middle point (indicated by a square numbered "2") between two vertically adjacent pixels 1b and 1a constituting each pixel pair in areas 32 defined by thin dotted lines.

The space sampling points are thus arranged in a lattice-like pattern, as shown in Figure 9, at the same intervals at which the pixels 1, 1, ... are arranged.

As shown in Figure 8, in the method of reading out signals for the above solid-state imaging device, the timing of both a final gate transfer pulse signal ϕ_{H1}' and a reset pulse signal ϕ_R is set so as to synchronize with a horizontal CCD drive pulse signal ϕ_{H1} and a horizontal CCD drive pulse signal ϕ_{H2} with the same clock cycle. Therefore, every space sampling point is positioned at the middle point between two vertically adjacent pixels constituting each pixel pair. That is, the signal charge obtained from a given space sampling point represents combined signal charges of two vertically adjacent pixels.

However, with the recent advances toward increased pixel count and miniaturization of optics, the unit pixel area has been reduced to such a degree that the sensitivity characteristics of photoelectric converters under a low light intensity are now nearing the theoretical point where shot noise associated with

photoelectric conversion will become dominant. Therefore, the above method of reading out signals for a solid-state imaging device has the problem that since the signal charge of one space sampling point is obtained by combining signal charges of two vertically arranged pixels 1 and 1, the absolute signal charge amount is low per space sampling point, resulting in a drop in the signal-to-noise ratio under a low light intensity, and hence degradation in sensitivity characteristics.

SUMMARY OF THE INVENTION

The method of reading out signals of this invention for a solid-state imaging device comprising photoelectric conversion means and charge transfer means, said photoelectric conversion means having a plurality of pixels arranged in an array of rows and columns, each of said pixels converting light to signal charges, said charge transfer means receiving said signal charges and transferring said signal charges to an output of said device overcomes the above-discussed and numerous other disadvantages and deficiencies of the prior art. In this method of the invention, signal charges generated in a plurality of horizontally adjacent ones of said pixels are combined in said charge transfer means and outputted at said output in a combined form.

In a preferred embodiment, combinations of said plurality of horizontally adjacent ones of said pixels for combining the signal charges are periodically changed.

In a preferred embodiment, video signal conforming to the 2:1 interlaced scanning is produced by changing said combinations of said plurality of horizontally adjacent ones of said pixels for combining the signal charges between an odd-numbered field and an even-numbered field.

In a preferred embodiment, timing of reset clock signal for resetting said signal charges is synchronized with two clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of two horizontally adjacent pairs of said pixels are outputted at said output.

In a preferred embodiment, timing of final gate transfer clock signal and timing of reset clock signal for resetting said signal charges are synchronized with two clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of two horizontally adjacent pairs of said pixels are outputted at said output.

In a preferred embodiment, timing of reset clock signal for resetting said signal charges is synchronized with three or more clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal

charges of three or more horizontally adjacent ones of said pixels are outputted at said output.

In a preferred embodiment, timing of final gate transfer clock signal and timing of reset clock signal for resetting said signal charges are synchronized with three or more clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of three or more horizontally adjacent ones of said pixels are outputted at said output.

Thus, the invention described herein makes possible the objective of providing a method of reading out signals for a solid-state imaging device, which can enhance the sensitivity under a low light intensity in a simple and inexpensive way without modifying the structure of the solid-state imaging device or adding an external device.

BRIEF DESCRIPTION OF THE DRAWINGS

This invention may be better understood and its numerous objects and advantages will become apparent to those skilled in the art by reference to the accompanying drawings as follows:

Figures 1A and 1B are clock timing charts of an embodiment according to the invention, Figure 1A is for an odd-numbered field and Figure 1B for an even-numbered field;

Figures 2 and 3 both show the arrangement of space sampling points in which the space sampling points for every horizontal scan are aligned from one scanning line to the next within the same field;

Figures 4 and 5 show the arrangement of space sampling points when the arrangement of space sampling points on the scanning lines for the same field is offset between each horizontal scan; Figure 6 shows a schematic diagram of an interline transfer charge-coupled (CCD) area/image sensor as an example of a two-dimensional solid-state imaging device in which 2:1 interlacing is achieved by a field-integration method;

Figure 7 is a cross sectional view of the horizontal transfer section 4, transfer gate 6, and charge detector 5 of Figure 6, with applied potentials indicated;

Figure 8 shows a clock timing chart of a prior art method; and

Figure 9 shows the arrangement of space sampling points in the prior art method.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The preferred embodiments of the present invention will now be described in detail with reference to the accompanying drawings.

Figures 1A and 1B are clock timing charts of this

embodiment for the horizontal transfer section 4 shown in Figure 6: Figure 1A is for an odd-numbered field and Figure 1B for an even-numbered field. The following detailed description deals with a method of reading out signals according to this embodiment with reference to Figures 1, 6, and 7.

In this embodiment, the timing of a final gate transfer clock signal ϕ_{H1}' applied to the final transfer electrode 14 of the transfer gate 6 (see Figure 7) and the timing of a reset clock signal ϕ_R applied to a reset transistor 22 (see Figure 7) are both synchronized with two clock cycles of both horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , as shown in the clock timing chart of Figure 1 for the horizontal transfer section 4. Thus, when the horizontal CCD clock signal ϕ_{H1} goes low and the horizontal CCD clock signal ϕ_{H2} goes high at time (a) in Figure 1A, the final gate transfer clock signal ϕ_{H1}' goes low, causing the potential profiles in a region 18 to vary as shown by a thin dotted line in Figure 7. This causes the signal charge held at the region 18 and pertaining to the immediately preceding pixel pair to be transferred to a floating diffusion layer 21 in the charge detector 5 where the signal charge is converted to a voltage for output through the amplifier 7.

Next, at time (b), the final gate transfer clock signal ϕ_{H1}' goes high, making the potential at the region 18 higher than that at a region 20, as shown by a thin solid line, and thus preventing the signal charge transferred to the region 18 from being transferred to the floating diffusion layer 21. At the same time, the horizontal CCD clock signal ϕ_{H1} goes high and the horizontal CCD clock signal ϕ_{H2} goes low, causing the potential profiles under electrodes 10, 11, 12, and 13 to vary as shown by a thick solid line in Figure 7, so that the signal charge transferred from one pixel pair and held at a region 16 and the signal charge transferred from another pixel pair and held at a region 15 are now transferred to the regions 18 and 17, respectively. Thus, the signal charge transferred from said one pixel pair is stored at the region 18. Thereafter, at time (c), the horizontal CCD clock signal ϕ_{H1} goes low and the horizontal CCD clock signal ϕ_{H2} goes high, causing the potential profiles under the electrodes 10, 11, 12, and 13 to vary as shown by a thick dotted line in Figure 7, so that the signal charge transferred from said other pixel pair and stored at the region 17 at time (b) is now transferred to the region 16. At this time, since the final gate transfer clock signal ϕ_{H1}' is kept high, the signal charge of said one pixel pair, transferred to the region 18 at time (b), remains held at the region 18.

Next, at time (d), the horizontal CCD clock signal ϕ_{H1} again goes high and the horizontal CCD clock signal ϕ_{H2} goes low, so that the signal charge of said other pixel pair, transferred to the region 16 at time (c), is now transferred to the region 18. In this manner, the signal charge of said one pixel pair, which has been held at the region 18 since time (b), is combined with

the signal charge of said other pixel pair horizontally adjacent to said one pixel pair. At the same time, the reset clock signal ϕ_R goes high to reset the potential of the floating diffusion layer 21 in the charge detector 5 to the reference level.

Thereafter, at time (e), the final gate transfer clock signal ϕ_{H1}' goes low, so that the signal charge representing the combined signal charges of the two pixel pairs and held at the region 18 is now transferred to the floating diffusion layer 21 in the charge detector 5 where the signal charge is converted to a voltage. Then, an output signal OS is output which represents the potential difference between the potential based on the combined signal charges of the four pixels 1 and the reference potential. At the same time, the horizontal CCD clock signal ϕ_{H1} goes high and the horizontal CCD clock signal ϕ_{H2} goes low, initiating the transfer operation of signal charges pertaining to the next combination of two horizontally adjacent pixel pairs.

As described above, the signal charges from the two horizontally adjacent pixel pairs comprising a total of four pixels 1 are combined to obtain a signal charge pertaining to one space sampling point. As a result, in this embodiment, the space sampling points for an odd-numbered field are each taken, as shown in Figure 2, at the middle point (indicated by a circle numbered "1") between four horizontally and vertically adjacent pixels 1, 1, ... in each region 41 defined by a thin solid line. On the other hand, the space sampling points for an even-numbered field are each taken at the middle point (indicated by a square numbered "2") between four horizontally and vertically adjacent pixels 1, 1, ... in each region 42 defined by a thin dotted line.

As is apparent from the comparison between the timing diagrams of Figures 1A and 1B, for an even-numbered field the timing to set the final gate transfer clock signal ϕ_{H1}' low and the timing to set the reset clock signal ϕ_R high are delayed by one clock cycle of the horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , compared to the timing for an odd-numbered field. The combination of two horizontally adjacent pixel pairs for combining the signal charges is thus offset by one pixel in the horizontal direction between the odd-numbered field and the even-numbered field, thereby achieving, as shown in Figure 2, a staggered lattice-like arrangement of the apparent space sampling points. This arrangement better serves to prevent degradation in modulation transfer function (MTF) characteristics than when the space sampling points are arranged in a simple lattice-like pattern as shown in Figure 3.

By thus combining signal charges of four pixels to obtain a signal charge pertaining to one space sampling point, the signal charge amount can be increased in proportion to the increase of the photo-sensitive area of one space sampling point, thereby

achieving an improvement in the signal-to-noise ratio. That is, a higher sensitivity can be obtained for a low light intensity although the image resolution drops to a certain degree.

Figures 2 and 3 both show the arrangement of space sampling points in which the space sampling points for every horizontal scan are aligned from one scanning line to the next within the same field. On the other hand, Figures 4 and 5 show the arrangement of space sampling points when the arrangement of space sampling points on the scanning lines for the same field is offset between each horizontal scan. The numbers in the figures indicate the scanning numbers. Figure 4 shows the arrangement in which the space sampling points for the same field are taken at the same points, while Figure 5 shows the arrangement in which the space sampling points for the same field are offset by one pixel in the horizontal direction between adjacent scanning lines. In either case, the space sampling points are arranged in a lattice-like pattern, at the same intervals at which the pixels 1 are arranged, which serves to prevent degradation in horizontal resolution that occurs with the arrangements of space sampling points shown in Figures 2 and 3. However, after sampling a signal charge pertaining to a given space sampling point, for example, a space sampling point 43, 44 of scanning number "1" in an odd-numbered field, it takes the time equivalent to four fields before sampling the signal charge pertaining to the same sampling point 43, 44, and hence, the resolution slightly drops in the case of a fast moving object.

As described, in the present embodiment, the timing of the final gate transfer clock signal ϕ_{H1}' and the timing of the reset clock signal ϕ_R are both synchronized with two clock cycles of the horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , as shown in the clock timing chart for the horizontal transfer section 4, for sampling signal charges from each pixel pair in the interline transfer CCD area/image sensor which is a two-dimensional solid-state imaging device. Therefore, the output signal OS supplied from the output terminal 8 is based on the combined signal charges obtained from two horizontally adjacent pixel pairs. By combining signal charges from two pixel pairs, the signal-to-noise ratio of luminance signal components can be improved (for example, shot noise is reduced by 3dB by combining signal charges from two pixel pairs), thereby providing enhanced sensitivity for applications where a low light intensity is used.

It should be noted, however, that the enhancement of sensitivity decreases the resolution to a certain degree, since the horizontal resolution decreases as the photosensitive area of one space sampling point increases. However, since the resolution of the human eye also tends to drop under a low light intensity, it does not present much of a problem.

Furthermore, in the present embodiment, when

obtaining the video signal conforming to the 2:1 interlaced scanning by offsetting the combination of two vertically adjacent pixels in the vertical direction between the odd-numbered field and the even-numbered field, the combination of two horizontally adjacent pixel pairs for combining the signal charges is periodically changed between each field or between adjacent scanning lines within the same field. In other words, the arrangement of apparent space sampling points is periodically shifted between each field or between adjacent scanning lines within the same field. This serves to prevent degradation in MTF characteristics.

Thus, according to the present embodiment, it is possible to enhance the sensitivity under a low light intensity in a simple and inexpensive way and prevents degradation in MTF characteristics without modifying the structure of the interline transfer CCD area/image sensor or adding an external device.

In the above embodiment, the timing of the final gate transfer clock signal ϕ_{H1}' and the timing of the reset clock signal ϕ_R are both synchronized with two clock cycles of the horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , to store the signal charges of two horizontally adjacent pixel pairs at the region 18 as shown in Figure 7. However, the present invention is not limited to the above clocking, but only the reset clock signal ϕ_R may be synchronized with two clock cycles of the horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , to achieve enhancement of sensitivity in a simpler manner.

In the above embodiment, the timing of the final gate transfer clock signal ϕ_{H1}' and the timing of the reset pulse signal ϕ_R are both synchronized with two clock cycles of the horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} , to combine the signal charges from two horizontally adjacent pixel pairs. However, the invention is not limited to the above clocking, but the timing of the final gate transfer clock signal ϕ_{H1}' and the timing of the reset clock signal ϕ_R may be so set as to synchronize with three or more clock cycles of the horizontal CCD clock signals ϕ_{H1} and ϕ_{H2} so that signal charges from three or more horizontally adjacent pixel pairs may be combined.

In the above embodiment, the horizontal transfer section 4 has been described as a two-electrode cell CCD array, but it will be appreciated that the invention is not restricted to this construction.

Also, in the description of the above embodiment, an interline transfer CCD area/image sensor is taken as an example, but it will be appreciated that the solid-state imaging device contemplated under the present invention is not limited to the one described above.

As is apparent from the above description, according to the method of reading out signals for a solid-state imaging device in the first embodiment of the invention, when reading out signal charges obtained by photoelectric conversion by photoelectric

conversion means comprising pixels, signal charges pertaining to a plurality of horizontally adjacent pixels are read out in a combined form, and therefore, the sensitivity under a low light intensity can be enhanced in a simple and inexpensive way without modifying the structure of the solid-state imaging device or adding an external device.

According to the method of reading out signals for a solid-state imaging device in the second embodiment of the invention, the method of the first embodiment is so adapted that the combination of a plurality of horizontally adjacent pixel pairs for combining the signal charges can be periodically changed, enabling the arrangement of apparent space sampling points to be shifted periodically. The second embodiment therefore provides the advantage, in addition to the advantages of the first embodiment, that degradation in MTF characteristics can be prevented.

It is understood that various other modifications will be apparent to and can be readily made by those skilled in the art without departing from the scope and spirit of this invention. Accordingly, it is not intended that the scope of the claims appended hereto be limited to the description as set forth herein, but rather that the claims be construed as encompassing all the features of patentable novelty that reside in the present invention, including all features that would be treated as equivalents thereof by those skilled in the art to which this invention pertains.

Claims

1. A method of reading out signals for a solid-state imaging device comprising photoelectric conversion means and charge transfer means, said photoelectric conversion means having a plurality of pixels arranged in an array of rows and columns, each of said pixels converting light to signal charges, said charge transfer means receiving said signal charges and transferring said signal charges to an output of said device, wherein signal charges generated in a plurality of horizontally adjacent ones of said pixels are combined in said charge transfer means and outputted at said output in a combined form.
2. A method according to claim 1, wherein combinations of said plurality of horizontally adjacent ones of said pixels for combining the signal charges are periodically changed.
3. A method according to claim 2, wherein video signal conforming to the 2:1 interlaced scanning is produced by changing said combinations of said plurality of horizontally adjacent ones of said pixels for combining the signal charges between

an odd-numbered field and an even-numbered field.

4. A method according to claim 1, wherein timing of reset clock signal for resetting said signal charges is synchronized with two clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of two horizontally adjacent pairs of said pixels are outputted at said output.
5. A method according to claim 1, wherein timing of final gate transfer clock signal and timing of reset clock signal for resetting said signal charges are synchronized with two clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of two horizontally adjacent pairs of said pixels are outputted at said output.
6. A method according to claim 1, wherein timing of reset clock signal for resetting said signal charges is synchronized with three or more clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of three or more horizontally adjacent ones of said pixels are outputted at said output.
7. A method according to claim 1, wherein timing of final gate transfer clock signal and timing of reset clock signal for resetting said signal charges are synchronized with three or more clock cycles of horizontal CCD clock signals for horizontally transferring said signal charges to said output, and said signal charges of three or more horizontally adjacent ones of said pixels are outputted at said output.
8. A solid-state imaging device comprising photoelectric conversion means having a plurality of pixels arranged in an array of rows and columns for converting light to signal charges, charge transfer means for receiving said signal charges and transferring said signal charges for output from said device, and control means for controlling the operation of the device such that signal charges generated in a plurality of horizontally adjacent ones of said pixels are combined and outputted from said device in a combined form.
